

v5.0.0

Released Q2 2026

PLATFORMS & APIS

- Linux
 - x64 · RHEL, Ubuntu
- Windows
 - x64 · code-signed binaries
- macOS
 - Apple Silicon (ARM64) only
- Languages
 - UXL · C · C++
- Roadmap
 - C# · iOS · Android · Industrial IoT

CRYPTO & COMPLIANCE

- AES-256
 - FIPS 140-3 validated · CMVP certificate
- Resilience
 - Dynamic scheme — quantum & AI resistant, no PKI

FIPS 140-3

ECCN 5D002

AES-256

No PKI

MIGRATING TO V5.0

- New license required — V4 licenses do not load
- Sertainty Agent removed
- API signatures changed — see release notes for details
- Global SSO & SMS-via-email removed
- Pre-5.0 objects still open; 5.0 objects won't open in V4

ACTIVE · INTELLIGENT · DATA

Data that protects itself

The Sertainty UXP Technology embeds **active intelligence** inside a protected object, preventing unauthorized access no matter where the data resides. Unlike conventional encryption, it constructs dynamic protection schemes that resist quantum systems and AI data-mining engines — securing data at rest, in flight, and in process.

Active Intelligence

Self-Protecting Files

Zero Trust Architecture

Offline by Default

THREE CORE OBJECTS

UXP Identity · .iic

Who can open

Authenticates a user, machine, or workgroup via challenge/response. Your credentials — treat like a private key, never share.

UXP Object · .uxp

What is protected

A self-enforcing container holding files, folders, or SQL data behind an embedded policy. The payload — safe to share anywhere.

SmartMessage

Peer-to-peer payload

A protected in-memory or on-disk message for direct exchange between identities — no containing file required.

FIRST ROUND-TRIP IN ~60 MINUTES

1

Install & license

Drop `sertainty.iic` in the standard location.
~5 min

2

Create an Identity

Define challenge pairs, privileges & optional machine ID.
~10 min

3

Package a UXP

Seal files with access rules, time-locks & geo-fences.
~10 min

4

Authenticate & extract

Satisfy the challenge loop; audit events written automatically.
~15 min

KEY CAPABILITIES

- Selective & partial access**
 - Who can read what — selective access governs page-level reach.
 - How much is unprotected — only the portion in use, at runtime.
 - How long plaintext exists — decrypted just in time, released after use.
- Active Intelligence, Active Authorization**

Every open triggers a fresh evaluation against the embedded rules: identity, time, location, device, and prior failures.

Access is never unconditional.
- UXP SQL**

SQLite-compatible relational data lives inside the UXP, with every query gated by the same Identity and rules that protect the file payload.
- Identity embedded at creation**

No external key store. The access policy is compiled into the UXP object at creation and travels with it.
- Offline by default. Airgap ready.**
 - No server, key manager, or network is needed for access decisions.
 - UXP runs identically in connected and airgapped environments.
 - Network features are opt-in.
- Event log & SIEM**

Logging is a preference set by the data owner. When the UXP is online, access events can be sent to a server through several outbound methods, ready for ingest by a SIEM or other monitoring tool. Storing the event log inside the UXP itself is also an option.
- Self-destruct & Alternate Reality**

Configurable defensive responses when access conditions fail: shred the contents, expose decoy data, or revoke the file silently.
- Delegate access without re-protecting**

Authorize and revoke users dynamically through the Delegate Service, without rebuilding or redistributing the UXP.
